Abstract:

Efforts to better understand anthropogenic and biogenic emissions of methane (CH₄), a greenhouse gas with a 100-yr global warming potential 25-fold greater than that of carbon dioxide, have become increasingly important as atmospheric CH₄ concentrations have grown to over 2.5 times pre-industrial levels. Landfills and natural gas distribution networks within cities have been shown to be significant CH₄ sources. The Indianapolis Flux Experiment (INFLUX), a multi-institution and multi-method campaign, has been evaluating top-down and bottom-up approaches for quantifying urban greenhouse gas emissions since 2008. The city of Indianapolis is an ideal testbed for studying urban emissions, given its isolation from other major cities and relatively simple topography and meteorology.

Airborne measurements of CH₄ in Indianapolis using Purdue University’s Airborne Laboratory for Atmospheric Research (ALAR), a light twin-engine aircraft instrumented for atmospheric observations, have been ongoing since 2008. To estimate city-wide emission rates of CH₄ from Indianapolis, our group uses a mass balance approach to quantify the city’s contribution of CH₄ relative to background levels. In addition to eight years of city-wide CH₄ emission rate estimates, we will discuss intra- and inter-annual trends in the magnitude of CH₄ emissions from Indianapolis.
